Abstract

A vertex $v \in V(G)$ is said to distinguish two vertices $x, y \in V(G)$ of a nontrivial connected graph G if the distance from v to x is different from the distance from v to y. A set $S \subset V(G)$ is a *local metric generator* for G if every two adjacent vertices of G are distinguished by some vertex of S. A local metric generator with the minimum cardinality is called a *local metric basis* for G and its cardinality, the *local metric dimension* of G. It is known that the problem of computing the local metric dimension of a graph is NP-Complete. In this paper we study the problem of finding exact values or bounds for the local metric dimension of strong product of graphs.

Keywords: Metric generator; metric dimension; local metric set; local metric dimension, strong product graph.

1 Introduction

A *metric generator* of a metric space (X, d) is a set $S \subset X$ of points in the space with the property that every point of X is uniquely determined by the distances from the elements of S. The *metric dimension* $\dim(X)$ of (X, d) is the smallest integer t such that there is a metric generator of cardinality t. A metric generator of cardinality $\dim(X)$ is called a *metric basis* of X.

The concept of metric dimension of a general metric space first appeared in 1953 in [3], but it attracted a little attention, except for the case of graphs. Given a simple and connected graph $G = (V, E)$, defined on the vertex set V and the edge set E, we consider the function $d_G : V \times V \to \mathbb{N} \cup \{0\}$, where $d_G(x, y)$ is the length of a shortest path between u and v and $\mathbb{N}$ is the set of positive integers. It is readily seen that (V, d_G) is a metric space.

The notion of metric dimension of a graph was introduced by Slater in [27], where the metric generators were called *locating sets*. Harary and Melter independently introduced the same concept in [14], where metric generators were called *resolving sets*. Applications of this invariant to the navigation of robots in networks are discussed in [18] and applications to chemistry in [16, 17]. This invariant was studied further in a number of other papers including, for instance [1, 5, 6, 9, 12, 15, 19, 25, 28]. Several variations of metric generators including resolving dominating sets [4], independent resolving sets [7], local metric sets [20], strong resolving sets [26], k-metric generators [8], simultaneous metric generators [21], etc. have since been introduced and studied.

In this article we are interested in the study of local metric generators, also called local metric sets [20]. A set S of vertices in a connected graph G is a *local metric generator* for G if every two adjacent vertices of G are distinguished by some vertex of S, *i.e.*, for every $u, v \in V(G)$ there exists $s \in S$ such that $d_G(u, s) \neq d_G(v, s)$. A local metric generator with the minimum cardinality is called a *local metric basis* for G and its cardinality, the *local metric dimension* of G, is denoted by $\dim_l(G)$. The following main results were obtained in [20].

Theorem 1. [20] *Let G be a nontrivial connected graph of order n. Then $\dim_l(G) = n - 1$ if and only if G is complete, and $\dim_l(G) = 1$ if and only if G is bipartite.*

The clique number $\omega(G)$ of a graph G is the order of a largest complete subgraph in G.

Theorem 2. [20] *Let G be connected graph of order n. Then $\dim_l(G) = n - 2$ if and only if $\omega(G) = n - 1$.*

The local metric dimension of graphs has been previously studied in [2, 10, 11, 20, 22, 23]. In particular, it was shown in [10, 11] that the problem of computing the local metric dimension is NP-Complete. This suggests finding the strong metric dimension for special classes of graphs or obtaining good bounds on this invariant. In this paper we study the problem of finding exact values or sharp bounds for the local metric dimension of strong product graphs.

We begin by giving some basic concepts and notations. For two adjacent vertices u and v of $G = (V, E)$ we use the notation $u \sim v$ and for two isomorphic graphs G and G' we use $G \cong G'$. For a vertex v of G, $N_G(v)$ denotes the set of neighbors that v has in G, *i.e.,* $N_G(v) = \{u \in V : \ u \sim v\}$. The set $N_G(v)$ is called the *open neighborhood of* v in G and $N_G[v] = N_G(v) \cup \{v\}$ is called the *closed neighborhood of* v in G.

We will use the notation K_n, $K_{r,s}$, C_n, N_n and P_n for complete graphs, complete bipartite graphs, cycle graphs, empty graphs and path graphs, respectively.

The strong product of two graphs $G = (V_1, E_1)$ and $H = (V_2, E_2)$ is the graph $G \boxtimes H = (V, E)$, such that $V = V_1 \times V_2$ and two vertices $(a, b), (c, d) \in V$ are adjacent in $G \boxtimes H$ if and only if

$a = c$ and $bd \in E_2$, or

$b = d$ and $ac \in E_1$, or

$ac \in E_1$ and $bd \in E_2$.

We would point out that the Cartesian product $G \Box H$ is a subgraph of $G \boxtimes H$ and for complete graphs $K_r \boxtimes K_s = K_{rs}$.

One of our tools will be a well-known result, which states the relationship between the vertex distances in $G \boxtimes H$ and the vertex distances in the factor graphs.

Remark 3. [13] *Let G and H be two connected graphs. Then*

$$d_{G\boxtimes H}((a, b), (c, d)) = \max\{d_G(a, c), d_H(b, d)\}.$$

For the remainder of the paper, definitions will be introduced whenever a concept is needed.

2 General Bounds

We begin by giving general bounds for the local metric dimension of strong product graphs.

Theorem 4. *Let G and H be two connected graphs of order $n_1 \geq 2$ and $n_2 \geq 2$, respectively. Then*

$$3 \leq \dim_l(G \boxtimes H) \leq n_1 \cdot \dim_l(H) + n_2 \cdot \dim_l(G) - \dim_l(G) \cdot \dim_l(H).$$

Proof. Let V_1 and V_2 be the set of vertices of G and H, respectively. We claim that $S = (V_1 \times S_2) \cup (S_1 \times V_2)$ is a local metric generator for $G \boxtimes H$, where S_1 and S_2 are local metric basis for G and H, respectively.

Let $(u_i, v_j), (u_k, v_l) \in V_1 \times V_2 - S$ be two adjacent vertices of $G \boxtimes H$. If $i = k$, then v_j and v_l are adjacent in H and there exists $b \in S_2$ such that $d_{G\boxtimes H}((u_i, b), (u_i, v_j)) = d_H(b, v_j) \neq d_H(b, v_l) = d_{G\boxtimes H}((u_i, b), (u_k, v_l))$. So, (u_i, v_j) and (u_k, v_l) are distinguished by $(u_i, b) \in (V_1 \times S_2) \subset S$. Analogously, if $j = l$, then u_i and u_k are adjacent in G and there exists $a \in S_1$ such that $d_G(a, u_i) \neq d_G(a, u_k)$ and, as above, (u_i, v_j) and (u_k, v_l) are distinguished by $(a, v_j) \in (S_1 \times V_2) \subset S$. Finally, if $u_i u_k \in E_1$ and $v_j v_l \in E_2$, then for any $a \in S_1$ such that $d_G(a, u_i) \neq d_G(a, u_k)$ we have

$$d_{G\boxtimes H}((u_i, v_j), (a, v_j)) = d_G(u_i, a) \neq d_G(u_k, a) = \max\{d_G(u_k, a), 1\} = d_{G\boxtimes H}((a, v_j), (u_k, v_l)).$$

Thus, (u_i, v_j) and (u_k, v_l) are distinguished by $(a, v_j) \in S_1 \times V_2 \subset S$. Then we conclude that S is a local metric generator for $G \boxtimes H$ and, as a consequence, $\dim_l(G \boxtimes H) \leq |S| = n_1 \cdot \dim_l(H) + n_2 \cdot \dim_l(G) - \dim_l(G) \cdot \dim_l(H)$.

To prove the lower bound, let B be a local metric basis of $G \boxtimes H$. Given $(u_1, v_1) \in B$, chose $u^* \in N_G(u_1)$, $v^* \in N_H(v_1)$ and define

$$W = \{(u^*, v_1), (u_1, v^*), (u^*, v^*)\}.$$

Since (u_1, v_1) is not able to distinguish any pair of adjacent vertices in W, there exists $(u_2, v_2) \in B - \{(u_1, v_1)\}$. Let

$$q = \min_{(a,b)\in W} \{d_{G\boxtimes H}((u_2, v_2), (a, b))\}.$$

Now, as $d_{G\boxtimes H}((a, b), (u_2, v_2)) \in \{q, q + 1\}$ for every $(a, b) \in W$, by Dirichlet's box principle, there are two vertices $(x_1, y_1), (x_2, y_2) \in W$ such that

$$d_{G\boxtimes H}((u_2, v_2), (x_1, y_1)) = d_{G\boxtimes H}((u_2, v_2), (x_2, y_2)).$$

Hence, $B - \{(u_1, v_1), (u_2, v_2)\} \neq \emptyset$, and the result follows. $\square$

Since $K_{n_1} \boxtimes K_{n_2} \cong K_{n_1 \cdot n_2}$ and for any complete graph K_n, $\dim_l(K_n) = n - 1$, we deduce

$$\dim_l(K_{n_1} \boxtimes K_{n_2}) = n_1 \cdot n_2 - 1 = n_1 \cdot \dim_l(K_{n_2}) + n_2 \cdot \dim_l(K_{n_1}) - \dim_l(K_{n_1}) \cdot \dim_l(K_{n_2}).$$

Therefore, the upper bound is tight. Examples of non-complete graphs, where the upper bound is attained, can be derived from Theorem 10.

In order to show that the lower bound is tight, consider two paths P_t and $P_{t'}$, where $t' \leq t \leq 2t' - 1$, $V(P_t) = \{u_1, u_2, \ldots, u_t\}$ and $u_i \sim u_{i+1}$, for every $i \in \{1, \ldots, t - 1\}$. Also, take $v_1, v_{t'} \in V(P_{t'})$ such that $d_{P_{t'}}(v_1, v_{t'}) = t' - 1$. It is not difficult to check that $\{(u_1, v_1), (u_{t'}, v_{t'}), (u_t, v_1)\}$ is a local metric generator for $P_t \boxtimes P_{t'}$, so that Theorem 4 leads to $\dim_l(P_t \boxtimes P_{t'}) = 3$.

3 The Particular Case of Adjacency k-Resolved Graphs

Now we will give some results involving the diameter or the radius of G. The *eccentricity* $\epsilon(v)$ of a vertex v in a connected graph G is the maximum distance between v and any other vertex u of H. So, the *diameter* of G is defined as

$$D(G) = \max_{v\in V(G)}\{\epsilon(v)\},$$

while the *radius* is defined as

$$r(G) = \min_{v\in V(G)}\{\epsilon(v)\}.$$

Given two vertices x and y in a connected graph $G = (V, E)$, the interval $I[x, y]$ between x and y is defined as the collection of all vertices which lie on some shortest $x - y$ path. Given a nonnegative integer k, we say that G *is adjacency* k*-resolved* if for every two adjacent vertices $x, y \in V$, there exists $w \in V$ such that

$d_G(y, w) \geq k$ and $x \in I[y, w]$, or

$d_G(x, w) \geq k$ and $y \in I[x, w]$.

For instance, the path and the cycle graphs of order n $(n \geq 2)$ are adjacency $\lceil \frac{n}{2} \rceil$-resolved, the two-dimensional grid graphs $P_r \Box P_t$ are adjacency $\left(\lceil \frac{r}{2} \rceil + \lceil \frac{t}{2} \rceil\right)$-resolved, and the hypercube graphs Q_k are adjacency k-resolved.

Theorem 5. *Let H be an adjacency k-resolved graph of order n_2 and let G be a non-trivial graph of diameter $D(G) < k$. Then* $\dim_l(G \boxtimes H) \leq n_2 \cdot \dim_l(G)$.

Proof. Let $V_1 = \{u_1, u_2, ..., u_{n_1}\}$ and $V_2 = \{v_1, v_2, ..., v_{n_2}\}$ be the set of vertices of G and H, respectively. Let S_1 be a local metric generator for G. We will show that $S = S_1 \times V_2$ is a local metric generator for $G \boxtimes H$. Let $(u_i, v_j), (u_r, v_l)$ be two adjacent vertices of $G \boxtimes H$. We differentiate the following two cases.
Case 1. $j = l$. Since $u_i \sim u_r$ and S_1 is a local metric generator for G, there exists $u \in S_1$ such that $d_G(u_i, u) \neq d_G(u_r, u)$. Hence,

$$d_{G\boxtimes H}((u_i, v_j), (u, v_j)) = d_G(u_i, u) \neq d_G(u_r, u) = d_{G\boxtimes H}((u_r, v_j), (u, v_j)).$$

Case 2. $v_j \sim v_l$. Since H is adjacency k-resolved, there exists $v \in V_2$ such that $(d_H(v, v_l) \geq k$ and $v_j \in I[v, v_l])$ or $(d_H(v, v_j) \geq k$ and $v_l \in I[v, v_j])$. Say $d_H(v, v_l) \geq k$ and $v_j \in I[v, v_l]$. In such a case, as $D(G) < k$, for every $u \in S_1$ we have

$$\begin{aligned} d_{G\boxtimes H}((u_i, v_j), (u, v)) &= \max\{d_G(u_i, u), d_H(v_j, v)\} \\ &< d_H(v, v_l) \\ &= \max\{d_G(u, u_r), d_H(v, v_l)\} \\ &= d_{G\boxtimes H}((u_r, v_l), (u, v)). \end{aligned}$$

Therefore, S is a local metric generator for $G \boxtimes H$. □

Lemma 6. *Let H be a connected bipartite graph of order greater than or equal to three. Then H is adjacency k-resolved for any $k \in \{2, .., r(H)\}$.*

Proof. Let $x, y, w \in V(H)$ such that $x \sim y$ and $d_H(x, w) = k$, for some $k \in \{2, .., r(H)\}$. Since H does not have cycles of odd length, $d_H(w, y) \neq k$. Thus, either $d_H(w, y) = d_H(w, x) + d_H(x, y) = k + 1$ or $d_H(w, x) = d_H(w, y) + d_H(y, x) = k$. Therefore, the result follows. $\square$

Now we derive a consequences of combining Theorem 5 and Lemma 6.

Theorem 7. *Let G and H be two connected non-trivial graphs. If H is bipartite and $D(G) < r(H)$, then* $\dim_l(G \boxtimes H) \leq |V(H)| \dim_l(G)$.

As we will show in Theorem 14, the above inequality is tight.

4 The Role of True Twin Equivalence Classes

Two vertices u and v of a graph G are true twins if $N_G[u] = N_G[v]$. Note that if two vertices u and v of a graph G are true twins, then $d_G(x, u) = d_G(x, v)$, for every $x \in V(G) - \{u, v\}$. We define the *true twin equivalence relation* $\mathcal{R}$ on $V(G)$ as follows:

$$x\mathcal{R}y \longleftrightarrow N_G[x] = N_G[y].$$

If the true twin equivalence classes are $U_1, U_2, ..., U_t$, then every local metric generator of G must contain at least $|U_i| - 1$ vertices from U_i, for each $i \in \{1, ..., t\}$. Thus the following result presented in [20] holds.

Theorem 8. [20] *If G is a nontrivial connected graph of order n having t true twin equivalence classes, then* $\dim_l(G) \geq n - t$.

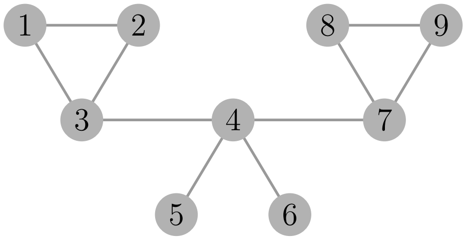

Figure 1: This graph has $t = 7$ true twin equivalence classes; two of them are $\{1, 2\}$ and $\{8, 9\}$ and the remain classes are singleton sets. A local metric basis is $\{1, 9\}$ while a metric basis is $\{1, 5, 9\}$. Thus, $\dim_l(G) = n - t = 2 < 3 = \dim(G)$.

Note that the complete graph has only one true twin equivalence class and in any triangle-free graph all the true twin equivalence classes are singleton. As an example of non-complete graph G of order n having t true twin equivalence classes, where $\dim_l(G) = n - t$, we take $G = K_1 + \left(\bigcup_{i=1}^{l} K_{r_i} \right)$, $r_i \geq 2$, $l \geq 2$. In this case G has $t = l + 1$ true twin equivalence classes, $n = 1 + \sum_{i=1}^{l} r_i$ and $\dim_l(G) = \sum_{i=1}^{l}(r_i - 1) = n - t$. Figure 1 shows another example of graph where the bound given in Theorem 8 is reached.

Lemma 9. *Let G and H be two non-trivial connected graphs of order n_1 and n_2, having t_1 and t_2 true twin equivalent classes, respectively. Then the vertex set of $G \boxtimes H$ is partitioned into $t_1 t_2$ true twin equivalent classes.*

Proof. First of all, we would point out that for any $a \in V(G)$ and $b \in V(H)$ it holds

$$N_{G\boxtimes H}[(a,b)] = \{(x,y):\ x \in N_G[a], y \in N_H[b]\} = N_G[a] \times N_H[b].$$

Now, since the result immediately holds for complete graphs, we assume that $G \ncong K_{n_1}$ or $H \ncong K_{n_2}$. Let $U_1, U_2, ..., U_{t_1}$ and $U'_1, U'_2, ..., U'_{t_2}$ be the true twin equivalence classes of G and H, respectively. Since each U_i (and U'_j) induces a clique and its vertices have identical closed neighbourhoods, for every $a, c \in U_i$ and $b, d \in U'_j$,

$$N_{G\boxtimes H}[(a,b)] = N_G[a] \times N_H[b] = N_G[c] \times N_H[d] = N_{G\boxtimes H}[(c,d)].$$

Hence, $V(G) \times V(H)$ is partitioned as $V(G) \times V(H) = \bigcup_{j=1}^{t_2} \left(\bigcup_{i=1}^{t_1} U_i \times U'_j \right)$, where $U_i \times U'_j$ induces a clique in $G \boxtimes H$ and its vertices have identical closed neighbourhoods. Moreover, for any $(a,b) \in U_i \times U'_j$ and $(c,d) \in U_k \times U'_l$, where $i \neq k$ or $j \neq l$, we have

$$N_{G\boxtimes H}[(a,b)] = N_G[a] \times N_H[b] \neq N_G[c] \times N_H[d] = N_{G\boxtimes H}[(c,d)].$$

Therefore, the true twin equivalence classes of $G \boxtimes H$ are of the form $U_i \times U'_j$, where $i \in \{1, .., t_1\}$ and $j \in \{1, .., t_2\}$. □

We would point out that the above result was indirectly obtained in [24], proof of Theorem 2.3.

Theorem 8 and Lemma 9 directly lead to the next result.

Theorem 10. *Let G and H be two non-trivial connected graphs of order n_1 and n_2, having t_1 and t_2 true twin equivalence classes, respectively. Then*

$$\dim_l(G \boxtimes H) \geq n_1 n_2 - t_1 t_2.$$

By Theorems 1, 4 and 10 we deduce the following result.

Theorem 11. *Let G and H be two non-trivial connected graphs of order n_1 and n_2, having t_1 and t_2 true twin equivalence classes, respectively. Then the following assertions hold:*

(i) *If $\dim_l(G) = n_1 - t_1$ and $\dim_l(H) = n_2 - t_2$, then $\dim_l(G \boxtimes H) = n_1 n_2 - t_1 t_2$.*

(ii) *If $\dim_l(G) = n_1 - t_1$ and H is bipartite, then $n_2(n_1 - t_1) \leq \dim_l(G \boxtimes H) \leq n_2(n_1 - t_1) + t_1$.*

Since any complete graph K_n has only one true twin equivalence class, Theorem 11 leads to the next result.

Corollary 12. *Let H be a connected graph of order $n' \geq 2$ having t true twin equivalent classes. Then for any integer $n \geq 2$,*

$$\dim_l(K_n \boxtimes H) = nn' - t.$$

In particular, if H does not have true twin vertices, then

$$\dim_l(K_n \boxtimes H) = n'(n-1).$$

Note that if H is an adjacency k-resolved graph, for $k \geq 2$, then H does not have true twin vertices. Therefore, Theorems 10 and 5 lead to the following result.

Theorem 13. *Let H be an adjacency k-resolved graph of order n_2 and let G be a non-trivial connected graph of order n_1, having t_1 true twin equivalence classes and diameter $D(G) < k$. If $\dim_l(G) = n_1 - t_1$, then $\dim_l(G \boxtimes H) = n_2(n_1 - t_1)$.*

Our next result can be deduced from Corollary 6 and Theorem 13 or from Theorems 10 and 7.

Theorem 14. *Let H be connected bipartite graph of order n_2 and let G be a non-trivial connected graph of order n_1, having t_1 true twin equivalence classes. If $\dim_l(G) = n_1 - t_1$ and $D(G) < r(H)$, then $\dim_l(G \boxtimes H) = n_2(n_1 - t_1)$.*

5 The Particular Case of $P_t \boxtimes G$

In this section we assume that t is an integer greater than or equal to two and $V(P_t) = \{u_1, u_2, \dots, u_t\}$, where $u_i \sim u_{i+1}$, for every $i \in \{1, \dots, t-1\}$. In the proof of the next lemma we will use the notation $\mathcal{B}_r(x)$ for the closed ball of center $x \in V(G)$ and radius $r \geq 0$, *i.e.*,

$$\mathcal{B}_r(x). = \{y \in V(G) : \; d_G(x, y) \leq r\}.$$

Lemma 15. *Let G be a connected graph and let $t \geq 1$ be an integer. Let $u_{i_1}, u_{i_2}, \dots, u_{i_b}$ be the first components of the elements in a local metric basis of $P_t \boxtimes G$, where $i_1 \leq i_2 \leq \cdots \leq i_b$. Then the following assertions hold.*

(i) *$i_2 \leq D(G) + 1$ and $i_{b-1} \geq t - D(G)$.*

(ii) *For any $l \in \{1, \dots, b-2\}$, $i_{l+2} \leq 2D(G) + i_l$.*

(iii) *$i_3 \leq 2D(G) + 1$.*

Proof. Let B be a local metric basis of $P_t \boxtimes G$ and let $u_{i_1}, u_{i_2}, \dots, u_{i_b}$ be the first components of the elements in B, where $i_1 \leq i_2 \leq \cdots \leq i_b$. First of all, notice that $|B| = b$ and, by Theorem 4, $b \geq 3$.

We first proceed to prove (i). Suppose, for the contrary, that $i_2 > D(G) + 1$. Let $y, z \in V(G)$ such that $(u_{i_1}, y) \in B$ and $z \in N_G(y)$. If $i_1 \neq 1$, then no vertex in B is able to distinguish (u_1, y) and (u_1, z). Now, if $i_1 = 1$, then no vertex in B is able to distinguish (u_2, y) and (u_2, z). So, in both cases we get a contradiction. The proof of $i_{b-1} \geq t - D(G)$ is deduced by symmetry. Hence, (i) follows.

To prove (ii) we proceed by contradiction. Suppose that $i_{l+2} > 2D(G) + i_l$ for some $l \in \{1, \dots, b-2\}$. In such a case we have that $i_{l+1} > D(G) + i_l$ or $i_{l+2} > D(G) + i_{l+1}$. We suppose that $i_{l+1} > D(G) + i_l$, being the second case analogous. We now take $y, z \in V(G)$ such that $(u_{i_{l+1}}, y) \in B$ and $z \in N_G(y)$. Notice that $(u_{i_l + D(G)}, y)$ and $(u_{i_l + D(G)}, z)$ are adjacent.We differentiate the following cases for $(u_{i_k}, w) \in B$. If $k \leq l$, then $i_l + D(G) - i_k \geq D(G)$ and so

$$d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, y)) = i_l + D(G) - i_k = d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, z)).$$

If $k = l + 1$ and $i_{l+1} \neq i_{l+2}$, then $w = y$ and since $i_{l+1} > D(G) + i_l$, we have

$$d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, y)) = i_k - i_l - D(G) = d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, z)).$$

If $k = l + 1$ and $i_{l+1} = i_{l+2}$, then from the assumption $i_{l+2} > 2D(G) + i_l$ we have that $i_k - i_l - D(G) > D(G)$ and so

$$d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, y)) = i_k - i_l - D(G) = d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l + D(G)}, z)).$$

If $k \geq l+2$, then the assumption $i_{l+2} > 2D(G) + i_l$ leads to $i_k - i_l - D(G) > D(G)$ and so

$$d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, y)) = i_k - i_l - D(G) = d_{P_t \boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, z)).$$

Hence, no vertex in B is able to distinguish $(u_{i_l+D(G)}, y)$ from $(u_{i_l+D(G)}, z)$, which is a contradiction. Therefore, the proof of (ii) is complete.

Finally, we proceed to prove (iii). If $i_1 = 1$, then by (ii) we obtain $i_3 \leq 2D(G) + 1$. Hence, we assume that $i_1 > 1$. For contradiction purposes, suppose that $i_3 > 2D(G) + 1$. We differentiate two cases for $(u_{i_1}, v_1), (u_{i_2}, v_2) \in B$.

Case 1: $i_1 + i_2 - 2 > d_G(v_1, v_2)$. In this case $|\mathcal{B}_{i_1-1}(v_1) \cap \mathcal{B}_{i_2-1}(v_2)| \geq 2$ and so we take $\alpha, \beta \in \mathcal{B}_{i_1-1}(v_1) \cap \mathcal{B}_{i_2-1}(v_2)$ such that $\alpha \sim \beta$. For the pair of adjacent vertices $(u_1, \alpha), (u_1, \beta)$ we have

$$d_{P_t \boxtimes G}((u_{i_1}, v_1), (u_1, \alpha)) = i_1 - 1 = d_{P_t \boxtimes G}((u_{i_1}, v_1), (u_1, \beta))$$

and

$$d_{P_t \boxtimes G}((u_{i_2}, v_2), (u_1, \alpha)) = i_2 - 1 = d_{P_t \boxtimes G}((u_{i_2}, v_2), (u_1, \beta)).$$

So, neither (u_{i_1}, v_1) nor (u_{i_2}, v_2) distinguishes (u_1, α) from (u_1, β). Furthermore, for $i_r \geq i_3 > 2D(G) + 1$ and $(u_{i_r}, v_r) \in B$ we have

$$d_{P_t \boxtimes G}((u_{i_r}, v_r), (u_1, \alpha)) = i_r - 1 = d_{P_t \boxtimes G}((u_{i_r}, v_r), (u_1, \beta)).$$

Therefore, no vertex $(u_{i_r}, v_r) \in B$ distinguishes (u_1, α) from (u_1, β), which is a contradiction.

Case 2: $i_1 + i_2 - 2 \leq d(v_1, v_2)$. In this case we have

$$(D(G)+2-i_1)+(D(G)+2-i_2) = 2D(G)+2-(i_1+i_2-2) \geq 2D(G)+2-d(v_1,v_2) \geq D(G)+2.$$

Hence, there exist $\alpha, \beta \in \mathcal{B}_{D(G)+2-i_1}(v_1) \cap \mathcal{B}_{D(G)+2-i_2}(v_2)$ such that $\alpha \sim \beta$. For the pair of adjacent vertices $(u_{D(G)+2}, \alpha), (u_{D(G)+2}, \beta)$ we have

$$d_{P_t \boxtimes G}((u_{i_1}, v_1), (u_{D(G)+2}, \alpha)) = D(G) + 2 - i_1 = d_{P_t \boxtimes G}((u_{i_1}, v_1), (u_{D(G)+2}, \beta))$$

and

$$d_{P_t \boxtimes G}((u_{i_2}, v_2), (u_{D(G)+2}, \alpha)) = D(G) + 2 - i_2 = d_{P_t \boxtimes G}((u_{i_2}, v_2), (u_{D(G)+2}, \beta))$$

So, neither (u_{i_1}, v_1) nor (u_{i_2}, v_2) distinguishes $(u_{D(G)+2}, \alpha)$ from $(u_{D(G)+2}, \beta)$. For $i_r \geq i_3 > 2D(G) + 1$ and $(u_{i_r}, v_r) \in B$ we have

$$d_{P_t \boxtimes G}((u_{i_r}, v_r), (u_{D(G)+2}, \alpha)) = i_r - (D(G) + 2) = d_{P_t \boxtimes G}((u_{i_r}, v_r), (u_{D(G)+2}, \beta)).$$

Thus, no vertex $(u_{i_r}, v_r) \in B$ distinguishes $(u_{D(G)+2}, \alpha)$ from $(u_{D(G)+2}, \beta)$, which is a contradiction. $\square$

Theorem 16. *For any connected G and any integer $t \geq 2D(G) + 1$,*

$$\dim_l(P_t \boxtimes G) \geq \left\lceil \frac{t-1}{D(G)} \right\rceil + 1.$$

Proof. Let B be a local metric basis of $P_t \boxtimes G$ and let $u_{i_1}, u_{i_2}, \ldots, u_{i_b}$ be the first components of the elements in B, where $i_1 \leq i_2 \leq \cdots \leq i_b$. We differentiate two cases.

Case 1. b odd. In this case $b-1$ is even and by Lemma 15 (i) and (ii) we have

$$i_2 \leq D(G) + 1,\ i_4 \leq 3D(G) + 1,\ \ldots,\ i_{b-1} \leq (b-2)D(G) + 1.$$

Case 2. b even. In this case $b-1$ is odd and by Lemma 15 (iii) and (ii) we have

$$i_3 \leq 2D(G) + 1,\ i_5 \leq 4D(G) + 1,\ \ldots,\ i_{b-1} \leq (b-2)D(G) + 1.$$

According to the two cases above and Lemma 15 (i) we have

$$t - D(G) \leq i_{b-1} \leq (b-2)D(G) + 1.$$

Therefore, $b \geq \frac{t-1}{D(G)} + 1$. □

From now on we say that a set $W \subset V(G \boxtimes H)$ *resolves* the set $X \subseteq V(G \boxtimes H)$ if every pair of adjacent vertices in X is distinguished by some element in W.

Lemma 17. *Let G and H be two connected nontrivial graphs such that H is bipartite. Let $u_1, u_2, u_3 \in V(G)$ and $v_1, v_2 \in V(H)$ such that $u_2 \in I_G[u_1, u_3]$, $d_G(u_1, u_2) \leq d_H(v_1, v_2) = D(H)$ and $d_G(u_2, u_3) \geq D(H)$. Then, for any shortest path P from u_1 to u_2, the set $B = \{(u_1, v_1), (u_2, v_2), (u_3, v_1)\}$ resolves $V(P) \times V(H)$.*

Proof. Let P be a shortest path form u_1 to u_2 and let $(u_i, v_j), (u_k, v_l) \in V(G \boxtimes H)$ be two adjacent vertices such that $u_i, u_k \in V(P)$. Without lost of generality, we assume that $d_G(u_i, u_1) \leq d_G(u_k, u_1)$. Notice that from this assumption we have that $d_G(u_i, u_3) \geq d_G(u_k, u_3)$. We differentiate the following two cases:

Case 1: $u_i \sim u_k$. As $d_G(u_2, u_3) \geq D(H)$ and $u_i, u_k \in V(P)$, we have $D(H) \leq d_G(u_3, u_k) < d_G(u_3, u_i)$ and so $d_{G\boxtimes H}((u_3, v_1), (u_i, v_j)) = d_G(u_3, u_i) > d_G(u_3, u_k) = d_{G\boxtimes H}((u_3, v_1), (u_k, v_l))$.

Case 2: $i = k$. In this case $v_j \sim v_l$ and, as H is a bipartite graph, $d_H(v_1, v_j) \neq d_H(v_1, v_l)$ and $d_H(v_2, v_j) \neq d_H(v_2, v_l)$. We assume, without lost of generality, that $d_H(v_1, v_j) < d_H(v_1, v_l)$. Notice that

$$d_H(v_1, v_j) + d_H(v_j, v_2) \geq d_H(v_1, v_2) = D(H) \geq d_G(u_1, u_2) = d_G(u_1, u_i) + d_G(u_i, u_2).$$

Hence, $d_H(v_1, v_j) \geq d_G(u_1, u_i)$ or $d_H(v_j, v_2) > d_G(u_2, u_i)$. If $d_H(v_1, v_j) \geq d_G(u_1, u_i)$, then

$$d_{G\boxtimes H}((u_1, v_1), (u_i, v_j)) = d_H(v_1, v_j) < d_H(v_1, v_l) = d_{G\boxtimes H}((u_1, v_1), (u_k, v_l)).$$

Now, if $d_H(v_j, v_2) > d_G(u_2, u_i)$, then $d_H(v_l, v_2) \geq d_G(u_2, u_i) = d_G(u_2, u_k)$ and so

$$d_{G\boxtimes H}((u_2, v_2), (u_i, v_j)) = d_H(v_2, v_j) \neq d_H(v_2, v_l) = d_{G\boxtimes H}((u_2, v_2), (u_k, v_l)).$$

According to the cases above, the result follows. □

Theorem 18. *For any connected bipartite graph G and any integer $t \geq 2D(G) + 1$,*

$$\dim_l(P_t \boxtimes G) = \left\lceil \frac{t-1}{D(G)} \right\rceil + 1.$$

Proof. Let G and P_t be as in the hypotheses. From $\alpha = \left\lfloor \frac{t-1}{D(G)} \right\rfloor$ and two diametral vertices $a, b \in V(G)$ we define a set B_α as follows.

If $\alpha = \frac{t-1}{D(G)}$, then

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \dots, (u_{\alpha D(G)+1}, b)\}$$

for α is odd and

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \dots, (u_{\alpha D(G)+1}, a)\}$$

for α even.

If $\alpha < \frac{t-1}{D(G)}$, then

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \dots, (u_{\alpha D(G)+1}, b), (u_t, a)\}$$

for α odd and

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \dots, (u_{\alpha D(G)+1}, a), (u_t, b)\}$$

for α even. We would point out that, in any case, $|B_\alpha| = \left\lceil \frac{t-1}{D(G)} \right\rceil + 1$.

We will show that B_α is a local metric generator for $P_t \boxtimes G$. In order to see that, let (u_i, v_j) and (u_k, v_l) be two adjacent vertices belonging to $V(P_t \boxtimes G) - B_\alpha$. We consider, without lost of generality, that $i \leq k$ and we differentiate the following three cases for k.

- $1 \leq k \leq D(G)+1$. Let $T_1 = \{u_1, \dots, u_{D(G)+1}\} \times V(G)$. In this case $(u_i, v_j), (u_k, v_l) \in T_1$ and, by Lemma 17 the set $\{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a)\} \subset B_\alpha$ resolves T_1.
- $pD(G) + 2 \leq k \leq (p + 1)D(G) + 1$, for some integer $p \in \{1, ..., \alpha - 1\}$. Let $T_p = \{u_{pD(G)+1}, \dots, u_{(p+1)D(G)+1}\} \times V(G)$. In this case $(u_i, v_j), (u_k, v_l) \in T_p$ and we can take $x, y \in \{a, b\}$ so that $X_p = \{(u_{(p-1)D(G)+1}, x), (u_{pD(G)+1}, y), (u_{(p+1)D(G)+1}, x)\}$ is a subset of B_α. Thus, by Lemma 17 we can conclude that X_p resolves T_p.
- $\alpha D(G)+2 \leq k \leq t$. Let $T_t = \{u_{\alpha D(G)+1}, \dots, u_t\} \times V(G)$. As above, $(u_i, v_j), (u_k, v_l) \in T_t$ and we can take $x, y \in \{a, b\}$ so that the set $X_t = \{(u_{(\alpha-1)D(G)+1}, x), (u_{\alpha D(G)+1}, y), (u_t, x)\}$ is a subset of B_α. Thus, by Lemma 17 we can conclude that X_t resolves T_t.

According to the three cases above we have $\dim_l(P_t \boxtimes G) \leq \left\lceil \frac{t-1}{D(G)} \right\rceil + 1$. Therefore, by Theorem 16 we conclude the proof. □

The authors of [24] conjectured that for any integers t and t' such that $2 \leq t' < t$, the metric dimension of $P_t \boxtimes P_{t'}$ equals $\left\lceil \frac{t+t'-2}{t'-1} \right\rceil$. We are now able to prove the conjecture.

Theorem 19. *For any integers t and t' such that $2 \leq t' < t$,*

$$\dim(P_t \boxtimes P_{t'}) = \left\lceil \frac{t+t'-2}{t'-1} \right\rceil.$$

Proof. As pointed out in Section 2, for $t' \leq t \leq 2t' - 1$, $\dim_l(P_t \boxtimes P_{t'}) = 3$. Now, since $\dim_l(P_t \boxtimes P_{t'}) \leq \dim(P_t \boxtimes P_{t'})$, if $t \geq 2t' - 1$, then by Theorem 18 we obtain the lower bound $\dim(P_t \boxtimes P_{t'}) \geq \left\lceil \frac{t+t'-2}{t'-1} \right\rceil$. The upper bound was obtained in [24]. Therefore, the result follows. □

6 The Particular Case of $C_t \boxtimes G$

In this section we assume that t is an integer greater than or equal to three and $V(C_t) = \{u_1, u_2, \dots, u_t\}$, where $u_1 \sim u_t$ and $u_i \sim u_{i+1}$, for every $i \in \{1, \dots, t-1\}$.

Lemma 20. *Let G be a connected graph and let $t \geq 3$ be an integer. Let $u_{i_1}, u_{i_2}, \dots, u_{i_b}$ be the first components of the elements in a local metric basis of $C_t \boxtimes G$, where $i_1 \leq i_2 \leq \cdots \leq i_b$. Then for any $l \in \{1, \dots, b\}$, $d_{C_t}(u_{i_{l+2}}, u_{i_l}) \leq 2D(G)$, where the subscripts of i are taken modulo b.*

Proof. Let B be a local metric basis of $C_t \boxtimes G$ and let $u_{i_1}, u_{i_2}, \dots, u_{i_b}$ be the first components of the elements in B, where $i_1 = 1 \leq i_2 \leq \cdots \leq i_b$. First of all, notice that $|B| = b$ and, by Theorem 4, $b \geq 3$.

We proceed by contradiction. Suppose that $d_{C_t}(u_{i_{l+2}}, u_{i_l}) > 2D(G)$ for some $l \in \{1, \dots, b\}$. In such a case we have that $d_{C_t}(u_{i_{l+1}}, u_{i_l}) > D(G)$ or $d_{C_t}(u_{i_{l+2}}, u_{i_{l+1}}) > D(G)$. We suppose that $d_{C_t}(u_{i_{l+1}}, u_{i_l}) > D(G)$, being the second case analogous. We now take $y, z \in V(G)$ such that $(u_{i_{l+1}}, y) \in B$ and $z \in N_G(y)$. Notice that $(u_{i_l+D(G)}, y)$ and $(u_{i_l+D(G)}, z)$ are adjacent. We differentiate the following cases for $(u_{i_k}, w) \in B$. If $k \neq l+1$, then $d_{C_t}(u_{i_l+D(G)}, u_{i_k}) \geq D(G)$ and so

$$d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, y)) = d_{C_t}(u_{i_l+D(G)}, u_{i_k}) = d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, z)).$$

If $k = l+1$ and $i_{l+1} \neq i_{l+2}$ then $w = y$ and since $d_{C_t}(u_{i_{l+1}}, u_{i_l}) > D(G)$, we have

$$d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, y)) = d_{C_t}(u_{i_k}, u_{i_l+D(G)}) = d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, z)).$$

If $k = l+1$ and $i_{l+1} = i_{l+2}$ then from the assumption $d_{C_t}(u_{i_{l+2}}, u_{i_l}) > 2D(G)$ we have that $d_{C_t}(u_{i_k}, u_{i_l+D(G)}) > D(G)$ and so

$$d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, y)) = d_{C_t}(u_{i_k}, u_{i_l+D(G)}) = d_{C_t\boxtimes G}((u_{i_k}, w), (u_{i_l+D(G)}, z)).$$

Hence, no vertex in B is able to distinguish the adjacent vertices $(u_{i_l+D(G)}, y)$ and $(u_{i_l+D(G)}, z)$, which is a contradiction. Therefore, the proof is complete. $\square$

Theorem 21. *For any connected graph G and any integer $t \geq 1$,*

$$\dim_l(C_t \boxtimes G) \geq \left\lceil \frac{t}{D(G)} \right\rceil.$$

Proof. If $3D(G) \geq t \geq 1$, then $\left\lceil \frac{t}{D(G)} \right\rceil \leq 3$ and, by Theorem 4, the result follows. From now on we take $t > 3D(G)$. Let $u_{i_1}, u_{i_2}, \dots, u_{i_b}$ be the first components of the elements in a local metric basis B of $C_t \boxtimes G$, where $i_1 = 1 \leq i_2 \leq \cdots \leq i_b$. First of all, notice that $t + 1 - i_{b-1} = d_{C_t}(u_{i_1}, u_{i_{b-1}})$ and so Lemma 20 leads to $i_{b-1} \geq t + 1 - 2D(G)$. We now differentiate two cases.

Case 1. b even. In this case $b-1$ is odd and by Lemma 20 we have

$$i_3 \leq 2D(G) + 1,\ i_5 \leq 4D(G) + 1,\ \dots,\ i_{b-1} \leq (b-2)D(G) + 1.$$

Hence, $t + 1 - 2D(G) \leq i_{b-1} \leq (b-2)D(G) + 1$, so that $b \geq \frac{t}{D(G)}$.

Case 2. b odd. By Lemma 20 we have

$$i_3 \leq D(G)+1,\ i_4 \leq 3D(G)+1,\ \ldots,\ i_b \leq (b-1)D(G)+1.$$

Now, since $t+i_2-i_b = d_{C_t}(u_{i_2}, u_b) \leq 2D(G)$, we have

$$i_2 \leq 2D(G) - t + i_b \leq (b+1)D(G) - t + 1.$$

Hence,

$$i_2 \leq (b+1)D(G)-t+1,\ i_4 \leq (b+3)D(G)-t+1,\ \ldots,\ i_{b-1} \leq (2b-2)D(G)-t+1.$$

Thus, $t+1-2D(G) \leq i_{b-1} \leq (2b-2)D(G)-t+1$, so that $b \geq \frac{t}{D(G)}$. ☐

Theorem 22. *For any connected bipartite graph G and any integer $t \geq 4D(G)$,*

$$\dim_l(C_t \boxtimes G) \leq \left\lceil \frac{t}{D(G)} \right\rceil + 1.$$

Furthermore, if $\left\lceil \frac{t}{D(G)} \right\rceil$ is even, then

$$\dim_l(C_t \boxtimes G) = \left\lceil \frac{t}{D(G)} \right\rceil.$$

Proof. Let G and C_t be as in the hypotheses. From $\alpha = \left\lceil \frac{t}{D(G)} \right\rceil$ and two diametral vertices $a, b \in V(G)$ we define a set B_α as follows. If α is even, then

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \ldots, (u_{(\alpha-1)D(G)+1}, b)\}$$

and, if α is odd, then

$$B_\alpha = \{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a), (u_{3D(G)+1}, b), \ldots, (u_{(\alpha-1)D(G)+1}, a), (u_{(\alpha-1)D(G)+1}, b)\}.$$

Notice that $|B_\alpha| = \alpha$, for α even, and $|B_\alpha| = \alpha+1$, for α odd. We will show that B_α is a local metric generator for $C_t \boxtimes G$. In order to see that, let (u_i, v_j), (u_k, v_l) be a pair of adjacent vertices belonging to $V(C_t \boxtimes G) - B_\alpha$. We consider, without lost of generality, that $i \leq k$ and we differentiate the following three cases for k.

- $2 \leq k \leq D(G)+1$. Let $T_1 = \{u_1, \ldots, u_{D(G)+1}\} \times V(G)$. In this case $(u_i, v_j), (u_k, v_l) \in T_1$ and, by Lemma 17 the set $\{(u_1, a), (u_{D(G)+1}, b), (u_{2D(G)+1}, a)\} \subset B_\alpha$ resolves T_1.
- $pD(G)+2 \leq k \leq (p+1)D(G)+1$, for some integer $p \in \{1, ..., \alpha-2\}$. Let $T_p = \{u_{pD(G)+1}, \ldots, u_{(p+1)D(G)+1}\} \times V(G)$. In this case $(u_i, v_j), (u_k, v_l) \in T_p$ and we can take $x, y \in \{a, b\}$ such that $X_p = \{(u_{(p-1)D(G)+1}, x), (u_{pD(G)+1}, y), (u_{(p+1)D(G)+1}, x)\}$ is a subset of B_α. Thus, by Lemma 17 we can conclude that X_p resolves T_p.
- $(\alpha-1)D(G)+2 \leq k \leq t+1$. Let $T_t = \{u_{(\alpha-1)D(G)+1}, \ldots, u_{t+1}\} \times V(G)$. In this case, $(u_i, v_j), (u_k, v_l) \in T_t$ and we take the set $X_t = \{(u_{(\alpha-1)D(G)+1}, b), (u_1, a), (u_{D(G)+1}, b)\} \subset B_\alpha$. By Lemma 17 we can conclude that X_t resolves T_t.

According to the three cases above B_α is a local metric generator for $C_t \boxtimes G$ and so $\dim_l(C_t \boxtimes G) \leq |B_\alpha|$. Therefore, by Theorem 21 we conclude the proof. ☐
